

# Railways, Smart Technologies

The way forward

IRSE Australasia AGM & Conference – Adelaide 2016

# Movement Authorities - A systems framework

Peter Burns, PYB Consulting

***PYB Consulting***

# Overview

- Context
  - Generic Systems Framework
- Movement Authorities
  - What are they?
  - When can they be given
  - Process for putting in place and cancelling
- Protection
- Translating from fixed signal to newer technologies

# Figure 1 - Generic Systems Framework

PB 160315

This is the route setting functionality in a conventional interlocking. It is "intentions level" signalling.

This is the step in which the infrastructure gives the train permission to travel on the section of line.

This is the step where an authority is handed back through use or cancelled without being used.

This is the step where each resource is released and can be reallocated for a different purpose.

This addresses the operation of points and other objects with a physical presence in the world.

This includes traditional track vacancy detection, but includes other methods and other types of occupation.

This is what the train driver (with help from some signage) traditionally does.

This is what ensures the train remains within authority limits and that the insurance provided is sufficient. It is important to note that the train driver (by seeing and obeying signals) is the primary enforcer of authority limits.

This section covers miscellaneous other systems for protecting trains and passengers. Its coverage is general and systems extend beyond interlocking or train.

# Preconditions

- Before issuing a Movement Authority
  - Route (if any) must be set (satisfying route level tests)
  - Points (or other device) in position (aspect level tests)
    - “Detected” to the extent required by the type of authority
    - “Locked” to the extent required by the type of authority
  - Train understands the “road ahead”
    - “Route knowledge” to the extent required
  - Track ahead clear
    - To the extent required by the type of authority
  - Insurance in place
    - To the extent required by the type of authority

# What is an authority?

- An Authority is a Contract
  - Meeting of Minds
    - Common Understanding: Train v Infrastructure
  - Agreement between parties
    - Identified Train v Identified Infrastructure
    - Formal process
  - A Subject (Scope)
    - Arbitrary (in principle)
  - Terms and Conditions
    - The rules of the Rail Authority
    - Special conditions
  - Consideration

# Value of view

- Contract communication is Vital Communications
  - Where agreement between parties is required
- Extensive literature on what can go wrong
  - More flexible than fixed signals

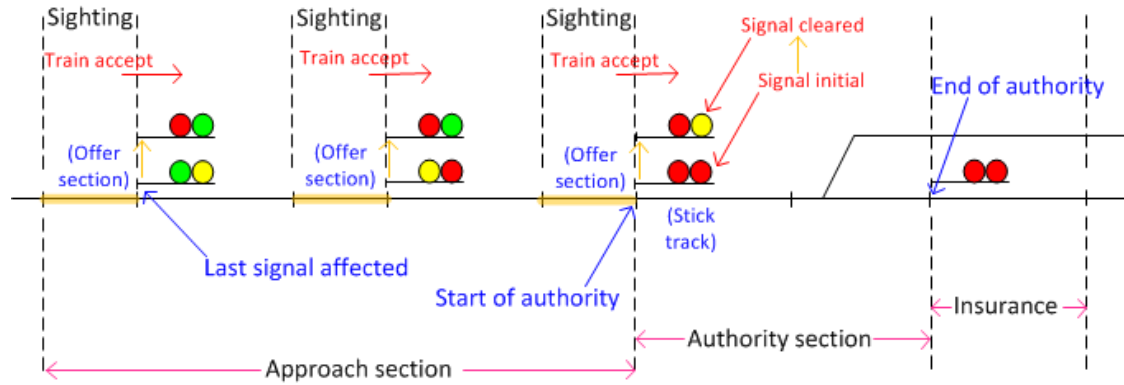

# Formal Process - 1

- Preliminary – “Invitation to treat”
  - Train in “sighting of signal” or in execution zone
- An offer (by the infrastructure)
  - Fixed signal displays proceed
  - Train order is read

Figure 2: Fixed signal sections

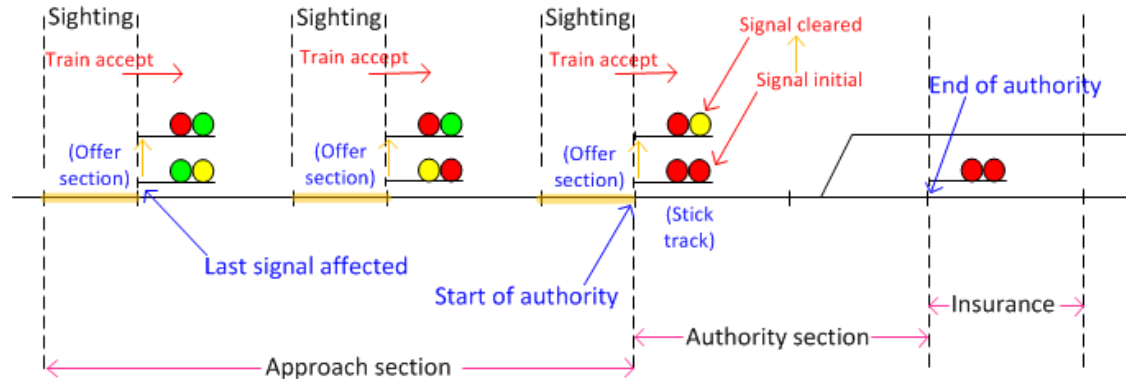

# Formal Process - 2

- An acceptance (by the train)
  - Train acts /or reads back authority
  
- Communication of acceptance
  - Train passes fixed signal
  - Controller hears order read back

Figure 2: Fixed signal sections

# Cancelling authority

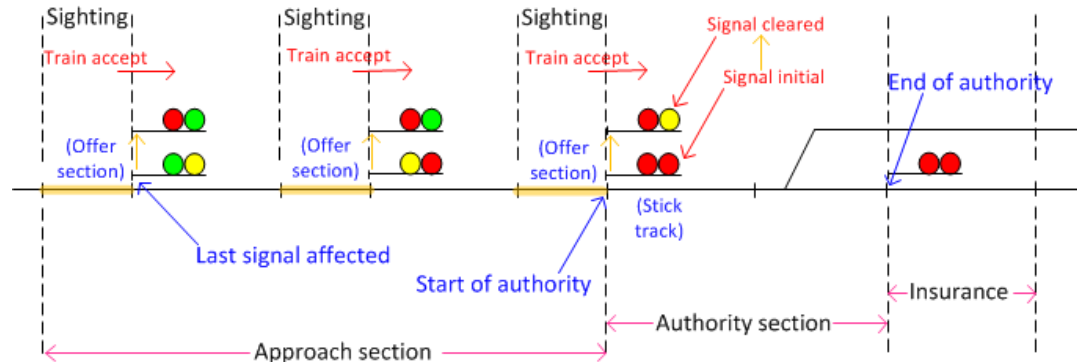

- Most authorities expire with performance
- Cancelling requires Contract Renegotiation
  - Offer = Button Pulled, Signal shows “Red”
  - Acceptance = Train Applies Brakes and stops
  - Communication of acceptance = Train stopped at signal
- Cancellation may be rejected as may any Contract Renegotiation
  - Train passes signal without stopping
    - Assume offer of original authority accepted instead
    - Offer to cancel (signal at stop) may not have been seen
    - Route locked, Authority cannot be withdrawn
- Process is seen in standard Approach Locking, but is more flexible
  - Splits, joins, reverses, stop shorts, speed restrictions are valid variants

# Insurance, memory and restart

- Insurance provided by the Overlap
  - Can be complex part of interlocking
  - Source of endless debate between Rail Authorities
  - Tends to dominate design effort
  
- Authority Area and Insurance Area are different
  - Option of “self insurance”
  
- Memory and Restart
  - Train can request information

Figure 2: Fixed signal sections

# Is ERTMS just ATP?

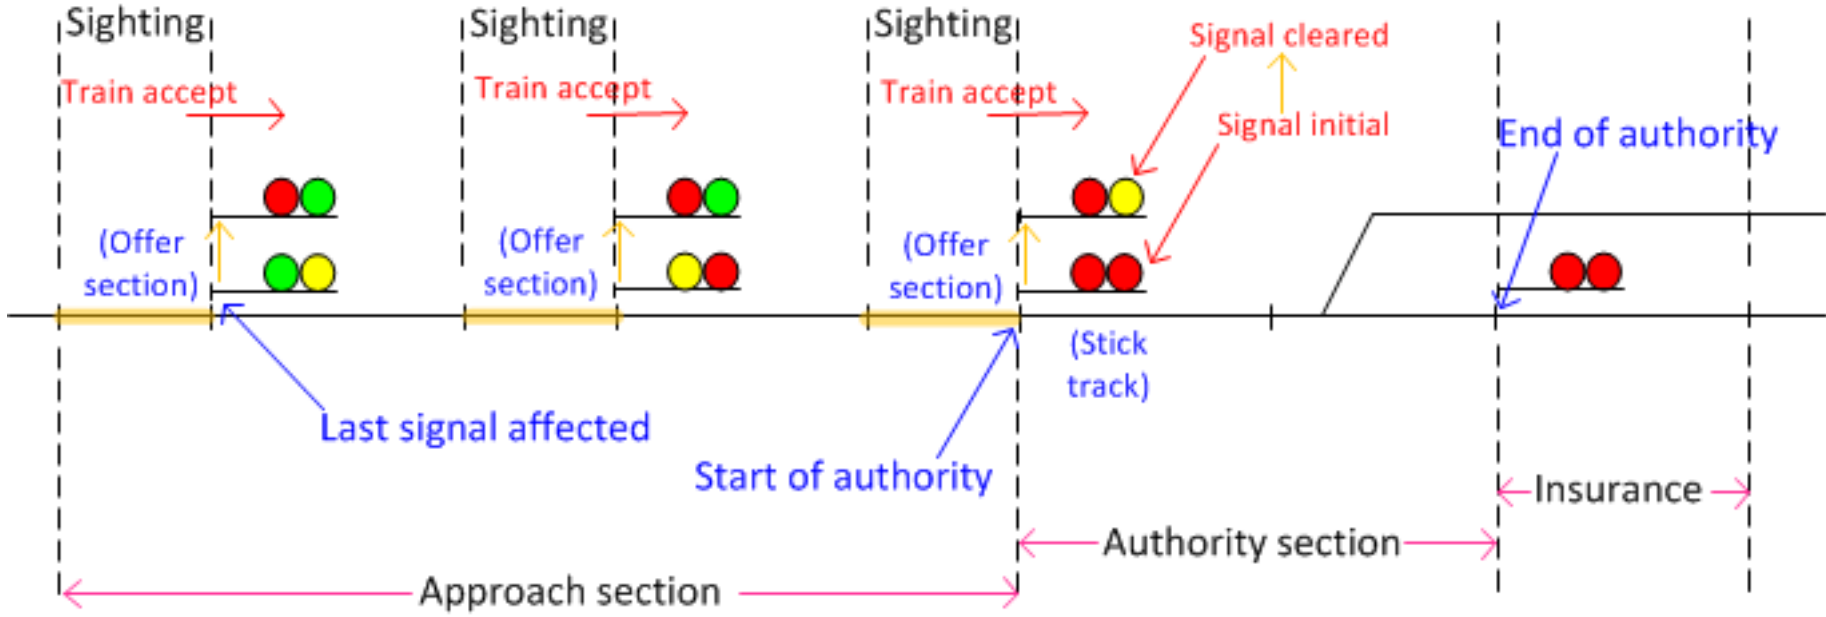

Figure 2: Fixed signal sections

# Protection

- Protection function separate from Authority function
  - Equipment Fault Detection
    - Fault detected
    - Signal reverts to stop (“failsafe” response)
    - Train Stops (best endeavours if signal seen)
    - Authority remains in place (Route protection remains)
  - Earthquake detection (Shinkansen)
    - Earthquake detected in substation
    - Overhead power switched off
    - Trains understand to brake to stop
    - (Signals not required)

# Fixed Signal Functions

- Regulate movement through interlocked areas
  - Traditional interlocking functions
  - Movement Authority process
- Regulate spacing between trains
  - Auto signals
  - ETCS and CBTC
  - Remove points?
- Inform trains of failures
  - “failsafe”

# Train separation

- Analogous to vehicles on road
  - Vehicle at rear responsible
    - Vehicle ahead visible
    - Vehicle can see and stop in time
  - Negotiation not required
  - Nothing to cancel
- Rail case
  - Yellow or distant signal provided
  - “Distance to go” concept provides “visibility”
- Protection issue or Authority?

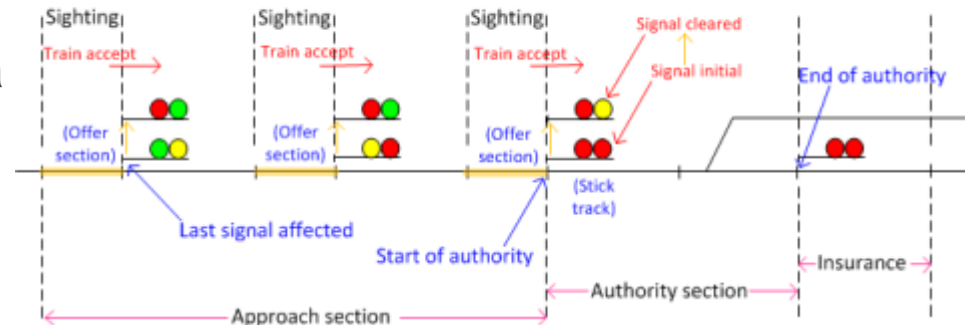

# Open & Closed Roads

- Single train authority
  - “Stick” provides train separation
  
- Multiple train authority
  - Multiple trains permitted between interlocked areas
  
- Absolute Permissive Block (APB)
  - Authority is for one direction at a time

Figure 2: Fixed signal sections

# ERTMS

- Train Separation uses Movement Authorities
  - New Authority every few seconds with high capacity
  - Communications constraint
  - Comms fault = Train stops (ERTMS level 2)

Figure 3: Closed road ETCS

# ERTMS & CBTC

- “ERTMS Regional” (level 3)
  - Designed for low density
  - “Distance to go” concept
  - Comms fault = train stops at end of authority
  - Tolerates intermittent communications
- CBTC
  - Designed for higher density
  - “Distance to go” concept
  - Comms fault = train stops at end of authority
  - Tolerates limited intermittency in communications
  - Insurance self management

# The Future

- Separate the three signal functions
  - Train separation as “Protection” function
    - Expand role of “on board” for ATP
  - Interlocking manages interlocked areas
    - Open Road Concepts

Figure 4: Open road concept

# Conclusion

- ERTMS and CBTC are today's technology
  - They excel where train separation is the goal
- Interlocking practice needs to keep up
  - Understanding of fundamentals will help the next generation
  - Good functional integration is possible
- Removing the points is not the only option
